Have you tested the installation of the software? How was the experience? Well, Installation Testing (Implementation Testing) is a pretty interesting part of testing the Life Cycle. Installation testing software as an introduction to your home. The new guest must be properly introduced to all family members to feel comfortable. Installing new software is also very similar to the above example. If your setup is successful on the new system then the customer will definitely be happy but that if things are completely opposite. If the installation fails, then our program will not work on this system not only this, but can leave the user's system badly damaged. The user may need to reinstall the entire operating system. In the above case did you impress the user? Definitely not! Your first impression is to make a loyal customer ruined due to incomplete installation testing. What do you need to do for a good first impression? Check the installer accordingly with a combination of both manual and automated processes on different machines with different configurations. The main problem with installing testing is time! It takes a long time to even run one test case. If you're going to test a large application installer, think about the time it takes to run so many test cases in different configurations. We will see different methods for performing manual installation testing and some basic guidelines for automating the installation process. To start testing the installation, first decide how many different system configurations you want to test the installation. Prepare one basic hard drive. The format of this HDD with the most common or file system by default, install the most common operating system (Windows) on this HDD. Install some basic essential components on this HDD. Each time creates images of this HDD base, and you can create other configurations on this base disk. Make one set of each configuration, such as the operating system and file format, to be used for further testing. How can we use automation in this process? Well, make some systems dedicated to creating basic images (use software like Norton Ghost to create accurate images of the operating system quickly) basic configuration. This will save you a lot of time in each test case. For example, if you set up one OS with a basic configuration for 1 hour, you'll need 1 hour for each test case on a fresh OS. But creating an OS image is unlikely to take 5 to 10 minutes, and you'll save about 40 to 50 minutes! You can use the same operating system with multiple installation attempts Each time the application is not installed and the base state is prepared for the next test case. Be careful here that your removal program should be checked up and should work normally. Installation testing tips with some broad test cases:#1) Use thread charts to perform installation testing. Flow diagrams simplify our See an example of a thread chart for the base test case of installation testing. Add a few more test cases on this basic flowchart For example, if our app isn't the first release, then try adding different logical ways to install.#2) If you've previously installed a compact base version of the app, then in the next test case, set the full version of the application in the same way as for the compact version.#3) If you use a thread chart to check the various files that will be written on the disk during installation, then use the same thread chart in reverse order to check the deletion of all installed files on disk.#4) Use the flow charts to automate the testing effort. It will be very easy to convert diagrams into automated scripts.#5) test the installation of scripts used to test the required disk space. If the installer is causing the required 1MB disk space, make sure that 1MB is used or more of the disk space used during installation. If so, mark this as an error.#6) Test disk space requirement on different file system formats. As FAT16 will require more space than effective NTFS or FAT32 file systems.#7) If it is possible to install a special system just to create image drive. As mentioned above, this will save you time testing.#8) Use a distributed testing environment to test the installation. The distributed environment simply saves you time and you can effectively manage all the different test cases from one machine. A good approach for this is to create a master machine that will drive different slave machines in the network. You can start installing simultaneously on another machine from master system.#9) Try to automate the routine to check the number of files that will be recorded on the disc. You can save this list of files that will be written on the disc in the Excel sheet and can give this list as input into an automated script that will check every way to check the correct installation.#10) Use the software available freely on the market to check registry changes on a successful installation. Checking registry changes with the expected list of changes after installation.#11) force you to break the installation process between them. Look at the behavior of the system and whether the system is recovering to its original state without any problems. You can test this installation break at every stage of the installation.#12) Disk Space Check: This is a crucial test in the test installation scenario. You can choose a variety of manual and automated methods for this check. In manual methods, you can check the free disk space available on the drive before installing and drive the space informed by the installer script to check whether the installer is calculating and disk space for sure. Check the disk space after installation to check the exact use of the drive installation space. Run a different combination of disk space availability with some tools to automatically make the drive space complete while installing. Check Check Out Behavior on low disk space during #13) When checking the installation you can check for removal as well. Before each new iteration of the installation, make sure that all files written on the disk are deleted after deleting. Sometimes the removal routine only removes files from the latest updated installation, keeping the old version files intact. Also, check the ability to restart after manually deleted and forcibly not restart. I've reviewed many areas of the manual as well as the automated installation testing procedures. However, there are many areas you should focus on depending on the complexity of your software being installed. These unresolved important tasks include network installation, online installation, installation of patches, database verification for installation, general DLL installation and removal, etc. If you like this article, you would also like to subscribe to our email newsletter. Sometimes apps can misbehave because of missing or damaged files. Windows makes it easier to fix a program when it happens, or even completely remove a program from your system if you no longer use it. Repair program Repair program works by checking all the files in the program folder, replaces everything that needs to be fixed, and can even check/fix records in the registry. It goes through installing the program again, but tries to save any settings that you have done. Using the Hit Start control panel, enter the control panel in the search box and then click on the result. In the control panel window, click on the Program button. Next, click on the Program button and features. Now you have to see a list of all the desktop programs currently installed on your computer. Scroll through the list and select the program you want to repair. If this feature is available for this program (not all programs support it), you'll see the Repair button at the top of the list. Click on that button. One of the caveats of using this feature is the need to install a package still on your Windows computer to be able to start repairing the program. If you've already deleted it, you'll have to go to the website and re-download the installer. After pressing the Repair button, Windows must handle the rest and quietly repair the affected program. If you're going to see something next, follow the dialog windows until they're complete. With the Settings app, you can repair the program in the same way with the Settings app. This option contains a complete list of apps, including both Windows apps and traditional desktop programs. To get started, open the app click on Win1, and then click on the Apps button. By default, it should open apps and features, but if it isn't, select it from the list on the left. Next, from the list below, click on the app you want Then click on the Change button. You can also use the search bar to find the program much faster than scrolling through the list. Depending on the app will open master settings, make sure you have chosen Repair and then click on the next button. Follow the rest of the tips, and when it's over, the program will be reinstalled and repaired. Uninstalling program Uninstalling program can be useful to free up much needed space on the hard drive or whether the program is not functioning as it should after an attempt to repair, uninstalling the application may be the best option. This works just like you would be repairing the program, but instead of opting for a repair/change option, you'll use the Uninstall button. Using the control panel just as to repair the program, open the control panel of the programs and features to see a list of all the programs installed on your computer. Choose the program you want to remove from your computer and then click delete at the top of the list. You may be asked if you are sure you want to remove this program. Click Yes. Using the Settings app, you start with the headline Settings of the apps and features. Scroll through the list and select the app you want to delete. Click delete next to the app and then click delete again on the pop-up that appears. You can also use the search bar to find the program much faster than scrolling through the list. From here Windows will take care of the rest and safely remove the program from your computer.
